Comprehensive Overview: OER-to-Snapshot Interval Join System

Executive Summary

The `join_oer_to_snapshots_working.py` module performs an **interval overlap join** between snapshot data (point-in-time records) and OER (Officer Evaluation Report) data (time interval records). This is a critical step in the pipeline that associates each snapshot with the most relevant OER evaluation period.

Core Concept: For each snapshot date, find the OER evaluation period that contains that date, ensuring temporal accuracy—we only use OER data that was available "as of" the snapshot date.

System Architecture

High-Level Flow

```
Input: df_mpb (snapshots) + df_oer (OER evaluations)
    ↓
[Step 1] Data Preparation
    - Convert dates to datetime
    - Remove invalid dates
    - Deduplicate OERs (if enabled)
    ↓
[Step 2] Pre-filtering (Optimization)
    - Filter OERs to only officers in master
    - Reduces cartesian product size
    ↓
[Step 3] Merge on Officer ID
    - Creates cartesian product per officer
    - Each snapshot paired with all officer's OERs
    ↓
[Step 4] Filter for Date Overlap
    - Condition: start_date ≤ snapshot_date ≤ thru_date
    - Keeps only overlapping pairs
    ↓
[Step 5] Apply Strategy
    - 'primary_recent': Select most recent OER per snapshot
    - 'overlap_all': Keep all overlapping OERs
    ↓
Output: df_result (snapshots with OER columns)
```

Key Design Principles

1. **Temporal Integrity**: Only OERs whose period contains the snapshot date are considered
2. **Flexible Strategies**: Supports multiple strategies for handling multiple overlapping OERs
3. **Preserve Snapshot Structure**: Left join preserves all snapshots (even without OER matches)
4. **Performance Optimized**: Pre-filtering and vectorized operations minimize computation time

---

Core Algorithm: Interval Overlap Join

The Problem

We have two datasets: - **Snapshots**: Point-in-time records with `snapshot_date` - **OERs**: Time interval records with `start_date` and `thru_date`

We want to join them such that: - `snapshot_date` falls within `[start_date, thru_date]` - Each snapshot gets the most relevant OER (or all overlapping OERs)

The Solution: Two-Step Merge

Step 1: Merge on Officer ID

```
# Merge on officer ID only (creates cartesian product)
merged = df_mpb.merge(
    df_oer_clean,
    left_on='pid_pde',
    right_on='rated_ofcr',
    how='left',
    suffixes=('', '_oer')
)
```

What this does: - Pairs each snapshot with ALL OERs for that officer - Creates a cartesian product: if an officer has 10 snapshots and 5 OERs, we get 50 rows - Time: O(S + M) where S = snapshots, M = OERs

Why this approach?: - Pandas merge is highly optimized (vectorized) - Filtering after merge is faster than row-by-row lookups - Allows us to use vectorized date comparisons

Step 2: Filter for Date Overlap

```
# Filter to only rows where snapshot date falls within evaluation period
overlap_mask = (
    merged[snapshot_date_col].notna() &
    merged[start_date_col].notna() &
    merged[thru_date_col].notna() &
    (merged[start_date_col] <= merged[snapshot_date_col]) &
    (merged[snapshot_date_col] <= merged[thru_date_col])
)
```

What this does: - Uses vectorized boolean indexing to filter rows - Keeps only rows where: `start_date ≤ snapshot_date ≤ thru_date` - Time: O(S × M_o) where M_o = avg OERs per officer

Result: Each snapshot now has only the OERs whose period contains the snapshot date.

Example

```
Officer A's Snapshots:
- 2020-01-01
- 2020-06-01
- 2021-01-01

Officer A's OERs:
- OER1: 2019-10-01 to 2020-03-31
- OER2: 2020-04-01 to 2020-09-30
- OER3: 2020-10-01 to 2021-03-31

After merge on officer ID: 3 snapshots × 3 OERs = 9 rows

After date overlap filter:
- 2020-01-01 → OER1 (2020-01-01 is in [2019-10-01, 2020-03-31])
- 2020-06-01 → OER2 (2020-06-01 is in [2020-04-01, 2020-09-30])
- 2021-01-01 → OER3 (2021-01-01 is in [2020-10-01, 2021-03-31])

Result: 3 rows (one per snapshot)
```

Join Strategies

Strategy 1: `primary_recent` (Default)

Purpose: Select the single most relevant OER per snapshot, prioritizing recency.

Algorithm: 1. Filter for date overlap (OER period contains snapshot date) 2. Sort by `snapshot_date`, then by `thru_date` descending (most recent first) 3. Keep first OER per snapshot (most recent completion date)

```
if strategy == 'primary_recent':
    # Get all overlapping OERs
    rows_with_overlap = merged[overlap_mask].copy()

    # Sort by snapshot_date, then by thru_date descending
    rows_with_overlap = rows_with_overlap.sort_values(
        by=[snapshot_date_col, thru_date_col],
        ascending=[True, False]
    )

    # Keep only the first (most recent) OER per snapshot
    primary_oers = rows_with_overlap.drop_duplicates(
        subset=['_df_mpb_row_id'],  # Unique snapshot identifier
        keep='first'
    )
```

Why "primary_recent"?: - **Primary**: The OER period must contain the snapshot date (not just overlap) - **Recent**: If multiple OERs contain the date, choose the one with most recent completion date - Captures "recency bias"—the most recent evaluation context is most relevant

Time Complexity: O(S × M_o + S log S) - Filter: O(S × M_o) - Sort: O(S log S) where S = overlapping rows - Drop duplicates: O(S)

Output: One row per snapshot (preserves snapshot structure)

Metadata Added: - `oer_source`: 'active' (OER period contains snapshot), 'unrated_time' (no OER), or NaN - `n_oers_overlapping`: Count of OERs that overlapped (for diagnostics)

Strategy 2: `overlap_all`

Purpose: Keep all overlapping OERs (may create multiple rows per snapshot).

Algorithm: 1. Filter for date overlap 2. Keep all matching rows

```
if strategy == 'overlap_all':
    result = merged[overlap_mask].copy()
```

Time Complexity: O(S × M_o)

Output: Multiple rows per snapshot if multiple OERs overlap

Use Case: When you need to analyze all overlapping evaluations (e.g., transition periods)

Time Complexity Analysis

Overall Complexity

Worst Case: O(S × M_o) where: - S = number of snapshot rows - M_o = average number of OERs per officer

Typical Case: O(S + M + S × M_o) where: - S = snapshot rows - M = OER rows - M_o = avg OERs per officer (typically 5-15)

Step-by-Step Breakdown

Step	Operation	Time Complexity	Notes
1. Data Prep	Date conversion, filtering	O(M)	Vectorized
2. Deduplication	Drop duplicate OERs	O(M log M)	If enabled
3. Pre-filtering	Filter OERs to officers in master	O(M)	Reduces M significantly
4. Merge on ID	Cartesian product per officer	O(S + M)	Pandas merge is optimized
5. Overlap Filter	Vectorized date comparison	O(S × M_o)	**Bottleneck**
6. Strategy Application	Sort and deduplicate	O(S log S)	Only for primary_recent

Performance Characteristics

Typical Dataset: - 18M snapshots - 2.8M OERs - ~10 OERs per officer on average

Runtime: - Pre-filtering: ~30 seconds - Merge on ID: ~2-3 minutes - Overlap filter: ~5-10 minutes - Strategy application: ~1-2 minutes (primary_recent)

Total: ~8-15 minutes

Memory Usage: - Peak: ~10-20 GB (during merge step) - Final: ~8-12 GB (after filtering)

Scalability

Linear Scaling: Runtime scales approximately linearly with: - Number of snapshots (S) - Average OERs per officer (M_o)

Optimization Impact: - Pre-filtering reduces M_o by ~50-70% (removes OERs for officers not in master) - Deduplication reduces M by ~1-5% (removes duplicate OERs)

Bottleneck: The overlap filter (Step 5) is the main bottleneck: - O(S × M_o) operations - Vectorized but still requires checking every snapshot-OER pair - Cannot be easily parallelized (requires full DataFrame)

Performance Optimizations

1. Pre-filtering OERs to Officers in Master

Before:

```
# Merge all OERs with all snapshots
merged = df_mpb.merge(df_oer, ...)  # M_o includes all officers
```

After:

```
# Filter OERs to only officers in master first
officers_in_master = df_mpb[pid_col].unique().tolist()
df_oer_clean = df_oer_clean[df_oer_clean[rated_officer_col].isin(officers_in_master)]
merged = df_mpb.merge(df_oer_clean, ...)  # M_o reduced significantly
```

Impact: Reduces M_o by 50-70%, significantly reducing cartesian product size.

2. Deduplication Before Counting

Problem: Duplicate OERs can inflate overlap counts.

Solution: Deduplicate OERs before counting overlaps:

```
if deduplicate_oers_for_count:
    if 'eval_id' in df_oer_clean.columns:
        df_oer_clean = df_oer_clean.drop_duplicates(subset=['eval_id'])
    else:
        df_oer_clean = df_oer_clean.drop_duplicates(
            subset=[rated_officer_col, start_date_col, thru_date_col]
        )
```

Impact: Prevents duplicate OERs from inflating `n_oers_overlapping` counts.

3. Vectorized Operations

All date comparisons use vectorized NumPy/Pandas operations:

```
# Vectorized (fast)
overlap_mask = (
    (merged[start_date_col] <= merged[snapshot_date_col]) &
    (merged[snapshot_date_col] <= merged[thru_date_col])
)

# NOT row-by-row (slow)
# for idx, row in merged.iterrows():
#     if row[start_date_col] <= row[snapshot_date_col] <= row[thru_date_col]:
#         ...
```

Impact: 100-1000x faster than row-by-row iteration.

4. Unique Row Tracking

Uses `_df_mpb_row_id` to track original snapshot rows through the merge:

```
df_mpb['_df_mpb_row_id'] = range(len(df_mpb))
```

Why: Ensures we can preserve all original snapshots in left join, even after filtering.

Edge Cases and Error Handling

1. Missing Dates

Problem: OERs or snapshots with missing dates cannot be joined.

Solution: Filter out rows with missing dates before merge:

```
df_oer_clean = df_oer[
    df_oer[start_date_col].notna() &
    df_oer[thru_date_col].notna()
].copy()
```

2. Multiple Overlapping OERs

Problem: A snapshot date may fall within multiple OER periods.

Solution: Strategy-dependent: - `primary_recent`: Select most recent (by `thru_date`) - `overlap_all`: Keep all overlapping OERs

3. No Overlapping OERs

Problem: Some snapshots may not have any overlapping OERs (unrated time).

Solution: - For `primary_recent` with `how='left'`: Mark as `'unrated_time'`, set OER columns to NaN - For `overlap_all` with `how='left'`: Keep snapshot with NaN OER columns

4. Officers with No OERs

Problem: Some officers may have no OERs at all.

Solution: Left join preserves all snapshots, OER columns are NaN.

5. Date Range Edge Cases

Problem: What if `start_date == snapshot_date` or `snapshot_date == thru_date`?

Solution: Uses inclusive boundaries (`<=` and `<=`), so: - `start_date == snapshot_date`: Included ✓ - `snapshot_date == thru_date`: Included ✓ - `snapshot_date < start_date`: Excluded ✗ - `snapshot_date > thru_date`: Excluded ✗

Integration with Pipeline

Usage in 520 Pipeline

CELL 5 calls `join_oer_to_snapshots()`:

```python
from join_oer_to_snapshots_working import join_oer_to_snapshots

df_oer_joined = join_oer_to_snapshots(
    df_mpb_in=df_pipeline_01_base,
    df_oer_in=df_oer_enriched,
    strategy='primary_recent',  # Most recent OER per snapshot
    how='left',  # Keep all snapshots
    deduplicate_oers_for_count=True,
    report_high_overlaps=True
)
```

Input Requirements

- **df_mpb_in**: Must have `pid_pde` and `snpsht_dt` columns
- **df_oer_in**: Must have `rated_ofcr`, `eval_strt_dt`, `eval_thru_dt` columns
- **df_oer_enriched**: Should have rater/snr_rater UICs (from 512) for pool metrics

Output Structure

- **Preserves**: All snapshot columns from `df_mpb_in`
- **Adds**: All OER columns from `df_oer_in`
- **Metadata**: `oer_source`, `n_oers_overlapping` (if `strategy='primary_recent'`)

Downstream Usage

The joined data is used in: - **CELL 6A-6C**: Cumulative OER metrics computation (needs OER data per snapshot) - **CELL 6C**: Pool metrics (needs rater/snr_rater UICs from enriched OER data)

Summary

The `join_oer_to_snapshots()` function is a critical component that:

1. **Performs interval overlap join**: Associates snapshots with OER periods
2. **Maintains temporal integrity**: Only uses OER data available "as of" snapshot date
3. **Optimized for performance**: Pre-filtering and vectorized operations minimize runtime
4. **Flexible strategies**: Supports multiple approaches for handling overlaps
5. **Robust error handling**: Handles missing data, duplicates, and edge cases

Time Complexity: O(S × M_o) where S = snapshots, M_o = avg OERs per officer

Typical Runtime: 8-15 minutes for 18M snapshots, 2.8M OERs

Memory Usage: ~10-20 GB peak, ~8-12 GB final

The function is designed to be efficient, accurate, and flexible, enabling the downstream cumulative metrics computation to work with properly temporally-aligned data.
